

AI Usage Note

Fulfilment Hub — Operations Analyst Round 3 — Gayatri Vageesh Koparde

Which AI tools I used and how

I used Claude (Anthropic) as a build partner for this project. I described XYZ's fulfilment process and the specific problems listed in the brief, and worked with Claude to scope, design and build a single-page web application covering order status tracking, priority handling, two-warehouse inventory, and an issue log. I reviewed the generated code, tested every workflow myself (advancing orders through each stage, transferring stock between warehouses, triggering and resolving issues), and iterated on scope, layout and wording rather than accepting the first output as final.

Moments where I disagreed with or changed an AI suggestion

- 1 The first version tracked order status independently of actual stock levels. I asked for the “Picking” step to check main-warehouse quantity and automatically log an issue when stock is insufficient there — a tracker that doesn't reflect real stock wouldn't solve the “orders can't be packed” problem named in the brief, so this felt necessary rather than optional.
- 2 An early draft of the order detail view had a template-string bug where a stock figure rendered as literal code instead of a number. I caught this by actually clicking through the app rather than just reading the code, and had it corrected — a reminder that AI-written code still needs to be run, not just reviewed.
- 3 I added dedicated Picking / Packed / Staged / Shipped shortcuts in the navigation on top of the general Orders view, since warehouse staff each tend to work one stage at a time and shouldn't have to filter a full order list to see just their queue — even though this adds more nav items than a minimal build would, it maps more directly to how the floor actually works shift to shift.

What I chose to focus on, and why

Of the seven problems listed, I prioritised four that compound into the most operational risk: (1) no visibility into order status, (2) priority orders getting buried, (3) stock mismatches between the spreadsheet and the shelves, and (4) packed boxes or courier pickups getting lost. I left out real courier-API integration and barcode scanning, since a take-home demo doesn't need production integrations to prove the underlying workflow logic — dummy data was sufficient to demonstrate the application end to end.
